

Complement System In Neuronal Development And Plasticity WP5090

Since fgsea results are calculated based on the ranked logFC values, many fgsea results with $\text{padj} < .05$ do not contain any L-R DEGs. For our analysis, we have filtered out such results.

fgsea manhattan plot (top): Lowly ranked values (x-axis) have the highest, most positive logFC (y-axis).

Volcano plot (right): Opposite from above, the logFC (x-axis) shows negative values on left and positive values on right.

Volcano showing genes contributing to GSEA result

Microglia Pathogen Phagocytosis Pathway WP3937

Significant ($\text{padj} < .05$) fgsea results were filtered to those that contained a L-R DEG in the leading edge genes. These L-R DEGs did not have to be paired (sig. in both annotations), allowing for unique PRECAST cluster or Seurat cell type label results to emerge (if present).

fgsea manhattan plot (top): The rank position of L-R DEGs is indicated with a red asterisk.

Volcano plot (right): The L-R DEGs are indicated with a red asterisk.

Volcano showing genes contributing to GSEA result

Macrophage Stimulating Protein MSP Signaling WP5353

Significant ($\text{padj} < .05$) fgsea results containing a L-R DEG were further stratified by those results that also contain a paired L-R DEG in the leading edge genes. This will help distinguish the smaller number of sig. results that only contained layer-specific L-R DEGs that were not reproducible in the other annotation strategy.

fgsea manhattan plot (top): The rank position of paired L-R DEGs is indicated with a black asterisk. Any additional layer-specific L-R DEGs are also indicated with a red asterisk.

Volcano plot (right): As this example shows, it is possible for a L-R DEG to be significantly different in the opposite direction of the GSEA result.
